

Project Design Phase

Date	28 September 2026
Team ID	SWTID-2026-2867
Project Name	Script-Controlled ACL – Restrict Record Access Based on Field Value

1. Introduction

The design phase explains how the project will be implemented in ServiceNow. The system is designed to control user access to records based on **user roles** and the **Branch field value**.

2. System Design

The project will use ServiceNow ACLs to control different types of access.

The main access levels are:

- **Read** – View records
- **Create** – Create new records
- **Write** – Modify existing records
- **Delete** – Delete records

3. User and Role Design

A test user named **EEE User** will be created.

The following roles will be used:

- **bb1** – Used for Read access
- **bb2** – Used for Create access
- **bb3** – Used for Write access
- **bb4** – Used for Delete access

The required roles will be assigned to the test user.

4. Table Design

A custom table named **Institution Details** will be created.

The table will contain the following fields:

Field Name	Purpose
------------	---------

Student Name	Stores student name
--------------	---------------------

Field Name	Purpose
Roll Number	Stores student roll number
Faculty	Stores faculty information
Branch	Stores branch information
Email	Stores student email
Phone Number	Stores phone number
Description	Stores additional details

The **Branch** field will contain:

- ECE
- EEE
- CSE

5. ACL Design

ACLs will be created for the Institution Details table.

Read ACL

The Read ACL will use a script to check the **Branch** field. The EEE User will be allowed to view records where the Branch value is **EEE**.

Create ACL

The Create ACL will allow users with the **bb2** role to create records.

Write ACL

The Write ACL will control the modification of existing records based on the assigned role.

Delete ACL

The Delete ACL will allow users with the **bb4** role to delete records.

6. Testing Design

The ACL configuration will be tested by impersonating the **EEE User**.

The following will be checked:

- Whether the user can view EEE records.
- Whether restricted records are hidden.
- Whether the user can create records.
- Whether the user can modify records.
- Whether the user can delete records.

7. Expected Design Outcome

The designed system will provide controlled access to the Institution Details table. Users will only be able to perform actions that are permitted by their roles and the configured ACL conditions.

8. Conclusion

The project design provides a structured approach for implementing **script-controlled ACLs in ServiceNow**. It ensures that record access is controlled based on roles and field values.
